Introduction

- African coastal cities are vulnerable to climate change due to their high exposure, low adaptive capacity and high population density.
- Discussions about setting goals to limit global warming by a predefined threshold have been actively ongoing since the mid-1990s. COP16 in 2010 set this threshold at 2°C while COP21 set an ambitious 1.5°C target.
- Whilst several studies have investigated future projections of extreme climate over several African regions based on CORDEX simulations (Giorgi and Gutowski 2015), most of them focused on:
  - Impacts at the end of the 21st century (Abiodun et al., 2017; Dosio, 2017).
  - Based on results of either a single or small set of CORDEX simulations, mainly due to limited number of available simulations (Endriss et al., 2013; Dosio and Ponzi, 2015; Pinto et al., 2015).
  - In this study we:
    - utilized current and most complete CORDEX Africa ensemble consisting of 25 simulations under Representative Concentration Pathway (RCP) 8.5 – More robust than a single or small set of CORDEX simulations (McSweeney et al., 2015).
    - Analyzed the response to rainfall & temperature extremes over – Cape Town, Durban, Dar es Salaam, Maputo & Mombasa, when projected global temperatures reach 1.5°C and 2.0°C.

Data and Methods

Area of study:
- Spatially this study considers Southern Africa, defined as the region lying between 36°S to 10°-52°E, with focus on 5 coastal city regions.

Datasets:
- 25 CORDEX-Africa simulations driven by the RCP8.5 - comprises the largest ensemble and may also be considered the most realistic business-as-usual scenario given the current trajectory of greenhouse gas emissions (Taylor et al. 2012).

Methods:
- Global Warming Levels (GWLs): - Although different definitions exist in the literature, all generally start with some pre-industrial baseline and use an averaged window period e.g. 15, 20 or 30 years to compute departure from the baseline and arrive at the GWL of interest is reached.
  - The timing for these levels is commonly defined as a central period of a long enough period when global mean temperature reaches predefined anomalies (1.5, 2, 2.5°C etc.) relative to preindustrial levels (1861-1890 in this study) as it is available across all CMIPs historical simulations.
  - Given the RCM downscaled data begins at 1950 and that the RCP scenarios begin in 2006 we define our control period for the present/recent climate as 1971-2000. The corresponding 30-year period is then extracted from the downscaled RCM for analysis.

Timing of 1.5°C and 2.0°C global warming | CMIPs | Preindustrial: 1861-1890 | 30-yr window

Results

- There are several methodologies used to determine the robustness of climate change signal (Collins 2013). We consider a climate change signal robust if the following two conditions are fulfilled:
  - More than 80% of model simulations agree on the sign of the change.
  - The signal to noise ratio (SNR) ≥ 1.
- We analyzed mean precipitation and temperature fields as well as two extreme indices from the Expert Team on Climate Change Detection and Indices (ETCCDI):
  - Consecutive Dry Days (CDD) and Consecutive Wet Days (CWD).
- Analysis done both on annual and seasonal time scales.

Discussion

Table 1: Projected Annual (A) and seasonal (S, dominant season of each city) changes in temperature (Temp), precipitation (Precip), CDD and CWD (together with broad implications on Water sector (directly impacts other sectors - Agriculture, Health etc.) Double pointed arrow show that the change signal is NOT robust.

Fig 2: Annual changes in temperature (first row) & rainfall (second row) under 1.5 and 2.0°C global warming. First column shows annual mean temperature and rainfall for control period, second and third columns show differences in annual mean temperature and rainfall between future and CTL during 1.5 and 2°C GWLs, respectively and fourth column shows differences between 2 and 1.5°C. Hatching shows areas where at least 80% of the simulations agree on the sign of the change and SNR > 1. For temperature all grid boxes satisfy the two criteria and the hatching is not shown.

Conclusion

- Study region warms faster than the global mean, up to more than 1°C under the 1.5°C and ≥ 1.5°C under 2°C GWL compared to the control period.
- There is a general statistically insignificant decrease in the number of CWDs and increase in the average duration of CDD at the five cities.
- Further investigation required to ascertain whether the temperature increases will offset any benefit from increased rainfall at Durban, Dar es Salaam and Mombasa. These results suggest that actionable policies geared towards adaptive strategies to alleviate the impacts of global warming are needed.
